

User Manual

Data Management Portal — complete guide to every module

Generated on: 06/08/2026

Audience: database administrators, data teams and anyone who wants to manage their data

1. What the portal is

The portal brings a data team's governance records into one place: registered databases, access, changes, application inventory, backup policy, restore tests, data dictionary, integrations and jobs. It is a record of what the team agreed and what happened — **it does not connect to the managed databases**. That separation is deliberate: it ensures security (the portal never holds a production credential) and portability. The backend is plain PHP, no framework, running on MySQL, PostgreSQL, SQL Server or SQLite.

The product is white-label: whoever installs picks the name, logo, database engine and administrator in the **/setup** wizard, which writes the configuration and removes itself when done.

2. Getting started

On first run, with no configuration, the portal redirects to **/setup**: enter the project title, the database engine (choosing SQLite needs no external database), the connection details and the administrator login/password. When done, sign in with that account. As an administrator you create the other accounts under Users and set, for each, the role and the list of allowed modules.

3. Roles and permissions

The role says what a person can do; the module list says where. They combine: a write account only writes in the modules on its list.

Role	Can do
leitura	Reads the modules allowed for the account.
escrita	Reads and maintains records in the allowed modules.
admin	Everything write can, plus Users, Registry (lists), Email, Settings and Certification.
master	Everything admin can, plus the Audit trail, actions on another master and deleting certifications.

4. The central Databases registry

The **Bancos** module is the base of everything. Each database is registered once — name, hostname, engine, environment, IPv4/IPv6 addresses and ports, owner — and a database is unique by the hostname + name pair. The other modules (Access, Inventory, Backup, Restore, Dictionary and Jobs) pick the database instead of retyping server and name, and the hostname fills in automatically.

5. Governance modules

Access — who has access to what, with justification, requester, approver and planned review. Distinguishes user and service accounts and the account nature; the database comes from the Bancos registry.

Changes — log of structural changes (DDL, configuration, patch), with environment, type, script, rollback, approver, status and the affected databases (multi-select). Generates a period audit Report in PDF — scope, status summary and the list of changes — with download and e-mail.

Inventory — catalog of the applications and DBMS installed on the servers: version, edition, current service pack/patch and end of support. Each record keeps the history of applied patches (date, type, version, ticket and who installed it) and generates an Inventory Report in PDF in the Certification format — evidence of version and patch management for IT audit.

Backup — backup policy per database: criticality, type, frequency, time, retention, location, RPO and RTO.

Restore — record of restore tests — date, backup used, time, result and owner —, the proof that the backup actually restores.

Dictionary — business dictionary of columns (database, schema, table, column, type, classification, origin). Accepts CSV import, with a template to download.

Integrations — integrations between systems: source and destination (with IPs), mechanism, direction, frequency, data transferred, classification, criticality and technical/business owners.

Jobs — jobs, ETLs and scheduled routines: type, server, database, command steps, frequency, schedule windows, criticality, status and owner.

6. Access Certification

Under Administration, Certification cross-checks a database's REAL permissions against what is registered in Access — the basis of a periodic certification for external audit. The portal does not connect to the database: extraction is an external step, under the DBA's credential.

Step	What to do
1	Pick the database and the period. Engine buttons (SQL Server, MySQL, PostgreSQL) show the ready extraction query; a button downloads the CSV template.
2	Run the query on the database (under your credential) and export the result to CSV. The CSV carries the banco column.
3	Upload the CSV; the portal cross-checks against Access and flags the exceptions.
4	Generate the PDF report, download or e-mail it, and save it to the history.

The cross-check flags three situations: **undocumented access** (exists in the database, no record — high risk), **outdated records** (in the portal, missing in the database) and **compliance**, summarized in a banded compliance indicator (Poor 0–50%, Moderate 51–90%, Excellent 91–100%). The history sits alongside, with a date filter, bulk delete and each cycle's compliance %, and buttons to download or e-mail the report at any time — including past cycles.

An administrator records certifications, but only the master can delete them — preserving the trail, like the Audit. The portal keeps only the summary (counters and exceptions), never the raw permissions CSV.

7. Reports

The Reports section exports each module's data: CSV per module, PDF per module, or a full JSON with everything. Inventory has its own formal PDF (inventory and patch report, in the Certification style); the others come out as a table.

8. Administration

Users — creates and maintains accounts, with photo, network login, department and position. Allows bulk CSV import of accounts — they come in with the Leitura role and no modules, flagged "no access" until an administrator grants them.

Registry — manages the option lists used in the forms (types, statuses, criticalities, inventory categories, etc.), to standardize data entry.

Email — configures the SMTP server used to send reports; the password is stored encrypted (AES-256-GCM).

Settings — portal name and logo, session inactivity timeout and the audit trail retention.

Audit — trail of who did what, when and from which IP — visible to the master only.

Security — access monitoring and a checklist of environment best practices.

9. Documentation

The Documentation module delivers three PDFs in Portuguese and English: this manual, the API manual and the diagram with the internal database dictionary. They are generated from the code, so they track tool changes.
