Data Management Portal — guide to every module

Generated on: 06/08/2026

Audience: database administrators and data teams

1. What the portal is

Brings a data team's records into one place: registered databases, access, changes, inventory, backup, restore, dictionary, integrations and jobs. It does not connect to the managed databases — it is a record of what the team agreed and what happened.

2. Databases and the modules

Each database is registered once in the Bancos module (hostname, engine, environment, IPv4/IPv6) and reused across Access, Inventory, Backup, Restore, Dictionary and Jobs, which pick the database instead of retyping. Access distinguishes user and service accounts; Changes tags several affected databases; the Dictionary accepts CSV import.

The Inventory module catalogs the applications and DBMS installed on the servers — version, edition, current service pack/patch and end of support — and keeps, inside each record, the history of applied patches (date, type, version, ticket and who installed it). It generates an Inventory Report in PDF in the same format as the Certification (scope, status summary, inventory and patch history), serving as evidence of version and patch management for IT audit.

The Changes module also generates a period audit Report in PDF (scope, status summary and the list of changes with approver and result), with download and e-mail — the same delivery format as the Certification, for audit.

3. Users and permissions

Each account has a role (leitura, escrita, admin, master) and a list of allowed modules. The record stores photo, network login, department and position. The screen allows bulk CSV import of accounts, which come in with the Leitura role and no modules (flagged "no access" until an administrator grants them).

4. Access Certification

Under Administration, the module cross-checks a database's REAL permissions against what is registered in Access — the basis of a periodic certification for external audit. The portal does not connect to the database: extraction is an external step, under the DBA's credential.

Step	What to do
1	Pick the database and the period. Engine buttons (SQL Server, MySQL, PostgreSQL) show the ready extraction query; a button downloads the CSV template.
2	Run the query on the database (under your credential) and export the result to CSV. The CSV carries the banco column.
3	Upload the CSV; the portal cross-checks against Access and flags the exceptions.
4	Generate the PDF report, download or e-mail it, and save it to the history.

The cross-check flags three situations: undocumented access (exists in the database, no record — high risk), outdated records (in the portal, missing in the database) and compliance, with a banded compliance indicator (Poor, Moderate, Excellent). The history sits on the side, with a date filter and bulk delete, and buttons to download or e-mail the report at any time.

An administrator records certifications, but only the master can delete them from the history — preserving the trail, like the Audit. The portal keeps only the summary (counters and exceptions), never the raw permissions CSV.

5. Documentation

The Documentation module delivers three PDFs in Portuguese and English: this manual, the API manual and the diagram with the internal database dictionary. They are generated from the code, so they track tool changes.
